ABSTRACT

The systems and process of identification and information through one fixed application or series of applications tied to an identification card. Encoded with pertinent information the identity would be read at checkpoints throughout terminals of transit and checkpoints, and ports of entry and exit. Identification is read and verified and validated via databases; matching cardholder with identity. The identification encompases multiple tasks as well as the ability to communication with multiple databases in a set order. These databases may include but are not limited to ticketing, reservations, bag claim, frequent flight account, credit applications as well as Federal and local databases. The process works in conjuction with the identification to create and enable a challenge system, at each checkpoint

demanding each point be correctly transversed before

another may be accomplished. The series or pattern created

by this system ensures security by controlling the movement

of people in stages and at checkpoints: and the flow of the

required information. The link of information and its staged

communication between points create a sterile environment.

The identification also acts as positive identification for

the identification holder. The identification also

operates as a permanent ticket, boarding pass and baggage

claim. This is a technological art, by way of creating a

flow; an information stream which updates and verifies

through a pattern of steps and checkpoints with contact by

databases. This system and process applies technology to

combine information flows, tied to identification in a

secured medium and area. It advances technology by making

identification fluid, multi-task oriented and interactive.

This results in the creation of a sterile environment

through the control of movement.
